- Runtime support
- Compiler support

## → Hybrid Transactional Memory

## → Open issues & conclusions

# Compiling Atomic

Transactional memory accessed via STM read & write functions

- Compiler inserts appropriate calls
- Code generation, control flow, optimizations in later slides

STM tracks accesses & detects data conflicts

# Runtime Data Structures

## Per-thread

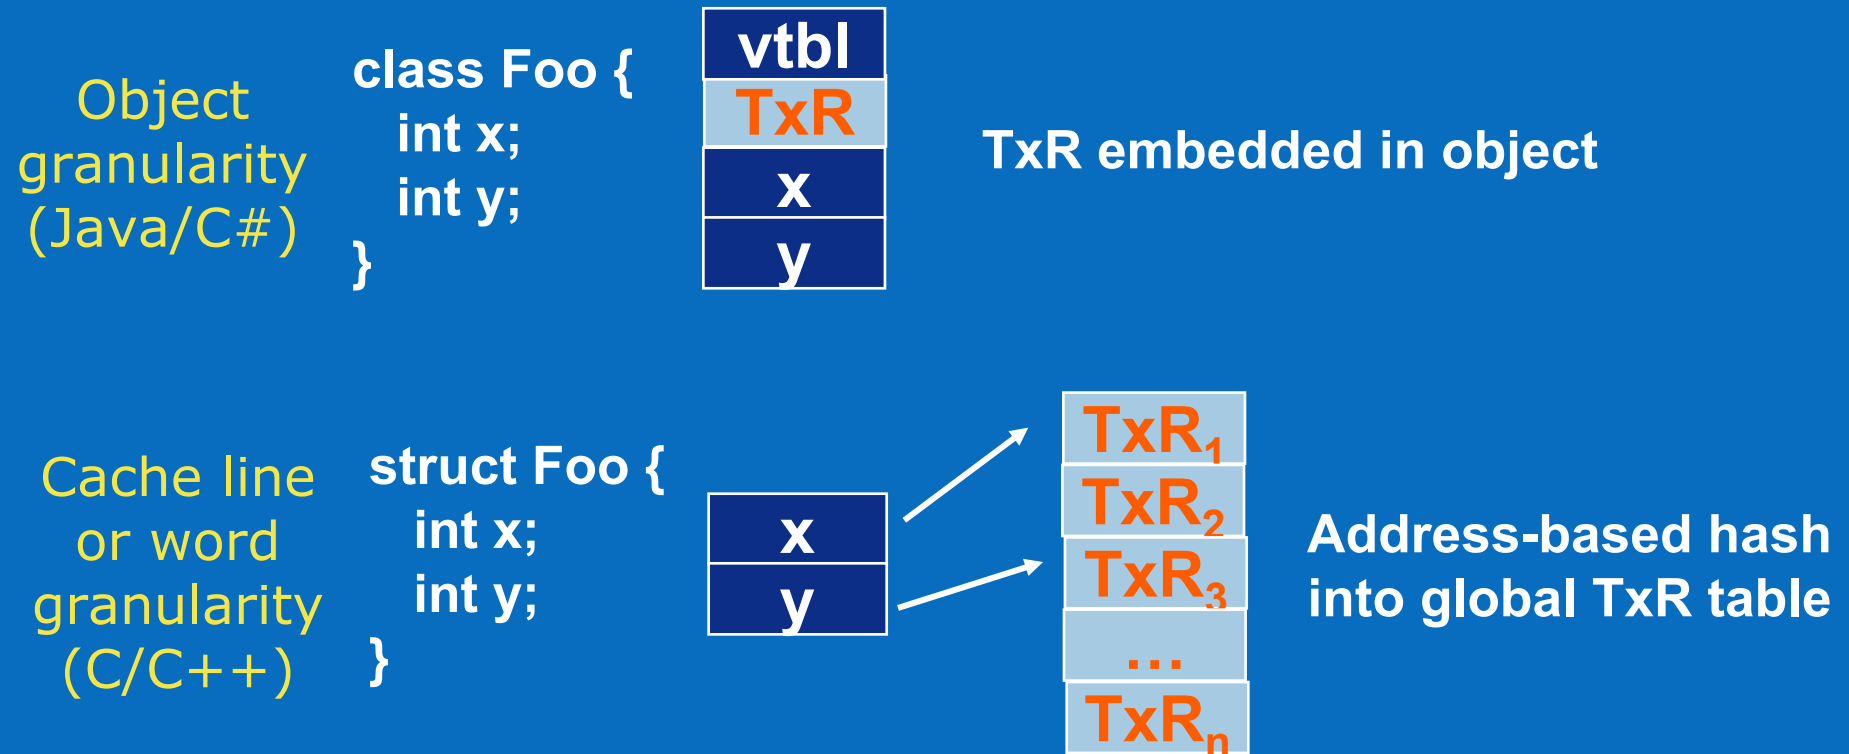

- Transaction Descriptor
  - Read set, write set, & log
  - For validation, commit, & rollback
- Transaction Memento
  - Checkpoint of transaction descriptor
  - For nesting & partial rollback

## Per-data

- Transaction Record (TxR)
  - Pointer-sized field guarding shared data
  - Track transactional state of data
    - Shared: Read-only access by multiple readers
    - Exclusive: write-only access by single owner

# Mapping Data to Transaction Records

Every data item has an associated transaction record

# Implementing Atomicity: Example

We will show one way to implement atomicity in a STM

Uses two phase locking for writes

Uses optimistic concurrency for reads

Illustrates how transaction records are used

# Example

# Ensuring Atomicity: Options

Memory Ops → Mode ↓	Reads	Writes
Pessimistic Concurrency	Read lock on TxR (reader-writer lock or reader list)	
Optimistic Concurrency	Use versioning on TxR	

# Ensuring Atomicity: Options

Memory Ops → Mode ↓	Reads	Writes
Pessimistic Concurrency	<ul style="list-style-type: none"><li>- Caching effects</li><li>- Lock operations</li></ul>	
Optimistic Concurrency	<ul style="list-style-type: none"><li>+ Caching effects</li><li>+ Avoids lock operations</li></ul>	

See Saha et al. PPOPP '06 paper for quantitative results

# Ensuring Atomicity: Options

Memory Ops → Mode ↓	Reads	Writes
Pessimistic Concurrency		Write lock on TxR
Optimistic Concurrency		Buffer writes & acquire locks at commit

# Ensuring Atomicity: Options

Memory Ops → Mode ↓	Reads	Writes
Pessimistic Concurrency		+ In place updates + Fast commits + Fast reads
Optimistic Concurrency		- Slow commits - Reads have to search for latest value

See Saha et al. PPOPP '06 paper for quantitative results

# Java Virtual Machine Support

On-demand cloning of methods called inside transactions

JIT compiler automatically inserts read/write barriers

- Maps barriers to first class opcodes in intermediate representation
- Good compiler representation → greater optimization opportunities
- Determine conflict detection granularity on per-type basis

Garbage collection support

- Enumeration of references in STM data structures
- Filtering to remove redundant log entries
- Mappings are valid across moving GC

# Representing Read/Write Barriers

Coarse-grain barriers hide redundant locking/logging

**atomic** {

    a.x = t1

    a.y = t2

    if(a.z == 0) {

        a.x = 0

        a.z = t3

    }

}

...

**stmWr**(&a.x, t1)

**stmWr**(&a.y, t2)

if(**stmRd**(&a.z) != 0) {

**stmWr**(&a.x, 0);

**stmWr**(&a.z, t3)

}

# An STM IR for Optimization

Redundancies exposed:

```
atomic {  
    a.x = t1  
    a.y = t2  
    if(a.z == 0) {  
        a.x = 0  
        a.z = t3  
    }  
}
```

```
txnOpenForWrite(a)  
txnLogObjectInt(&a.x, a)  
a.x = t1  
txnOpenForWrite(a)  
txnLogObjectInt(&a.y, a)  
a.y = t2  
txnOpenForRead(a)  
if(a.z != 0) {  
    txnOpenForWrite(a)  
    txnLogObjectInt(&a.x, a)  
    a.x = 0  
    txnOpenForWrite(a)  
    txnLogObjectInt(&a.z, a)  
    a.z = t3  
}
```

# Optimized Code

Fewer & cheaper STM operations

```
atomic {  
    a.x = t1  
    a.y = t2  
    if(a.z == 0) {  
        a.x = 0  
        a.z = t3  
    }  
}
```

```
txnOpenForWrite(a)  
txnLogObjectInt(&a.x, a)  
a.x = t1  
txnLogObjectInt(&a.y, a)  
a.y = t2  
if(a.z != 0) {  
    a.x = 0  
    txnLogObjectInt(&a.z, a)  
    a.y = t3  
}
```

# Compiler Optimizations for Transactions

## Standard optimizations

- CSE, Dead-code-elimination, ...
- Careful IR representation exposes opportunities and enables optimizations with almost no modifications
- Subtle in presence of nesting

## STM-specific optimizations

- Immutable field / class detection & barrier removal (vtable/String)
- Transaction-local object detection & barrier removal
- Partial inlining of STM fast paths to eliminate call overhead

# Effect of Compiler Optimizations

1P overheads over thread-unsafe baseline

Prior STMs typically incur  $\sim 2\times$  on 1P

With compiler optimizations:

- < 40% over no concurrency control
- < 30% over synchronization

# Hybrid TM: Combining HTM with STM

General approach:

- Try transaction using HTM first
- Fall back on STM if HTM aborts
- Atomic blocks multiversioned for HTM & STM execution

Accelerates simple transaction

- Small
- Flat transactions

STM-STM conflicts detected by the STM machinery

HTM-HTM conflicts detected by the HTM machinery

HTM-STM conflicts requires additional code in the HTM code path

# Hybrid TM: Basic Mechanism

HTMReadBarrier(*addr*)

check transaction record for *addr* is not locked by a SW transaction

if (transaction record free)

read the address

else

abort

HTMWriteBarrier(*addr*)

check transaction record for *addr* is not locked by a SW transaction

if (transaction record is free)

perform the write

increment version number to indicate HTM modification

else

abort

HTM check ensures no concurrent SW TM modification

# Research challenges

## Performance

- Right mix of HW & SW components
- Good diagnostics & contention management

## Semantics

- I/O & communication
- Nested parallelism

## Debugging & performance analysis tools

## System integration

# Conclusions

Multi-core architectures: an inflection point in mainstream SW development

Navigating inflection requires new parallel programming abstractions

Transactions are a better synchronization abstraction than locks

- Software engineering and performance benefits

Lots of research on implementation and semantics issues

- Great progress, but there are still open problems
